Good morning!

Interesting [KFF's survey](#) and New York Times article (attached).

Summary (AI generated, 😊) below:

About two-thirds of adults have used AI, but 56% lack confidence in distinguishing truth from falsehood in AI chatbot information, with 50% of regular AI users also expressing this doubt.

About one in six adults (17%) say they use AI chatbots at least once a month to find health information and advice, rising to one quarter of adults under age 30 (25%).

While about half of adults trust AI chatbots for practical information, only 29% trust them for health information and 19% for political information, with even AI users showing low trust (36% for health, 24% for politics).

While 23% of adults believe AI harms health information seeking and 21% think it helps, 55% of the public (including 49% of AI users) remain uncertain about AI's impact on finding accurate health information online.

What are your thoughts?

Best,

Pedro
